Grid Screen[™] PEG 6000

User Guide

Grid ScreenTM PEG 6000 is a preformulated reagent kit designed to provide a rapid screening method for the crystallization of biological macromolecules. The screen is simple and practical for finding initial crystallization conditions as well as determining the solubility of a macromolecule in Polyethylene glycol 6,000 between pH 4.0 and 9.0.

Sample Preparation

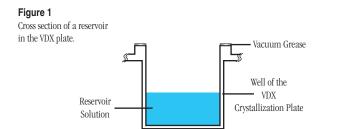

The macromolecular sample should be homogenous, as pure as is practically possible (>95%) and free of amorphous and particulate material. Remove amorphous material by centrifugation or micro-filtration prior to use. $^{(1,2,3)}$

The recommended sample concentration is 5 to 25 mg/ml in water. Initially, the sample should be free of any unnecessary additives in order to observe the effect of the Grid Screen PEG 6000 variables. Ideally, the initial screen should be performed with a sample which has been dialyzed against water although ligands, ions, reducing agents, or other additives may be present as required by the sample for solubility, stability, or activity.

Performing the Screen

Since it is the most frequently reported method of crystallization, the following procedure describes the use of Grid Screen PEG 6000 with the Hanging Drop Vapor Diffusion method. Grid Screen PEG 6000 is also very compatible with the Sitting Drop, Sandwich Drop, Microbatch, and Microdialysis methods. A complete description of the Hanging, Sitting, Sandwich Drop, Dialysis and other crystallization methods are available from the Hampton Research Crystal Growth 101 Library.

1. Prepare a VDX Plate (HR3-140 and HR3-142) for Hanging Drop Vapor Diffusion by applying a thin bead of cover slide sealant to the upper edge of each of the 24 reservoirs. One may also use a VDX[™] Plate with sealant (HR3-170 and HR3-172). Twenty-four reservoirs are to be prepared for a complete Grid Screen PEG 6000. See Figure 1.

2. Using a clean pipet tip, pipet 1 ml of Grid Screen PEG 6000 reagent A1 into reservoir A1. Discard the pipet tip, add a new pipet tip and pipet 1 ml of Grid Screen PEG 6000 reagent A2 into reservoir A2. Repeat the procedure for the remaining 22 Grid Screen PEG 6000 reagents using a clean pipet tip for each reagent so as to avoid reagent contamination and carry over.

HR2-213 (pg 1)

3. Pipet 2 μl of the sample to the center of a clean, siliconized 22 mm diameter circle or square cover slide. See Figure 2.

Figure 2

4. Pipet 2 μ l of Grid Screen PEG 6000 reagent A1 from reservoir A1 into the sample droplet and mix by aspirating and dispensing the droplet several times, keeping the tip in the drop during mixing to avoid foaming. See Figure 2.

5. Working quickly to minimize evaporation, invert the cover slide and droplet over reservoir A1 and seal the cover slide onto the edge of the reservoir. See Figure 3.

Figure 3 Inverted Siliconized Coverslip placed over the reservoir.

6. Repeat operations 3 through 5 for the remaining 23 Grid Screen PEG 6000 reagents.

7. If the quantity of sample permits, perform Grid Screen PEG 6000 in duplicate and incubate one set of plates at 4°C and the second set at room temperature. Incubate and store the crystallization plates in a stable temperature environment free of vibration.

Examine the Drop

Carefully examine the drops under a stereo microscope (10 to 100x magnification) immediately after setting up the screen. Record all observations and be particularly careful to scan the focal plane for small crystals. Observe the drops once each day for the first week, then once a week there after. Records should indicate whether the drop is clear, contains precipitate, and or crystals. It is helpful to describe the drop contents using descriptive terms. Adding magnitude is also helpful. Example: 4+ yellow/brown fine precipitate, 2+ small bipyramid crystals, clear drop, 3+ needle shaped crystals in 1+ white precipitate. One may also employ a standard numerical scoring scheme (Clear = 0, Precipitate = 1, Crystal = 10, etc). Figure 4 (on page 2) shows typical examples of what one might observe in a crystallization experiment.

Interpreting Grid Screen PEG 6000

Clear drops indicate that either the relative supersaturation of the sample and reagent is too low or the drop has not yet completed equilibration. If the drop remains clear after 3 to 4 weeks consider repeating the Grid Screen PEG 6000 condition and doubling the sample concentration. If more than 70%
