**Fixed Complement 3 (C3) Proceptor™ ELISA Kit Data Sheet**
*Product Code CC 003*

**INTRODUCTION**
The third complement component, C3 is a major complement factor due to its position in the classical, alternative, and lectin pathways and due to its relatively high concentration in the serum. The three pathways known to activate complement cascade lead to the formation of a convertase that cleaves C3 to C3a and C3b. The C3a is a known anaphylotoxin. The binding of C3b to immune complexes (ICs) facilitates the clearance of these proteins via binding through complement receptors present on the RBC. The deficiency of this complement protein is a known risk factor for the development of SLE. The serum levels of ICs, C3 and IgA along with other laboratory findings have been implicated as important markers for rheumatoid vasculitis.

Proceptor™ (CC-003) ELISA kit is the only available assay, which measures the total C3 component bound to circulating immune complexes (CICs). Assay provides a better indicator of immune status than the measurement of total serum C3, since the assay measures the complement protein actively involved in immune physiological process.

**ASSAY PRINCIPLE**
The assay is based on a unique capture of CICs by ProGen’s proprietary receptors (Proceptor™). These purified receptors are pre-coated on to the microtiter plate. To perform the test, an appropriate concentration of serum sample is incubated in the wells to allow binding of C3 containing CICs to the receptors. The C3 within the CIC is then measured using C3 specific antibody and HRP conjugated secondary antibody. After washing the plate, a substrate solution (TMB) is added to the wells for color development. Intensity of the color developed is proportionate to the amount of C3 protein bound to CICs.

**REAGENTS**
- **Receptor Microplate (3000103):** Polystyrene microplate (12X8 wells) coated with receptors* specific for CICs. Rows A1-H1 and A2-H2 are coated with varying concentrations of purified C3 protein standards. The standards are coated from 1.56 to 200 ng/ml, in doubling dilutions.
- **Anti-C3 Antibody (3000103) (Goat):** One bottle containing 1.2 ml (10X) of anti-C3 antibody (purified globulin fraction) with stabilization solution and preservative. Dilute with 1X wash buffer before use.
- **HRP Conjugate (1000703) (Donkey):** One bottle containing 12 ml of secondary antibody against C3 antibody. Purified immunoglobulin fraction conjugated to Horseradish peroxidase (HRP).
- **Color Development Reagent (1000901):** One bottle containing 12 ml of stabilized chromogen TMB (tetramethylbenzidine).
- **Stop Solution (1000801):** One bottle containing 7 ml of 0.25 N Sulfuric Acid.
- **Wash Buffer (1000601):** Two bottles each containing 50 ml of 10X PBS/Tween-20. Prepare a working solution of wash buffer by adding 50 ml of 10X wash buffer to 450 ml of deionized water to make 500 ml of 1X wash buffer. The 1X wash buffer can be used to wash the plate and to dilute samples.

**SAMPLE PREPARATION**
Suitable samples for C3 analysis by Proceptor™ ELISA: Human plasma treated with heparin and human serum. EDTA treated plasma is not recommended for the assay. Serum or plasma is diluted 1:50 to 1:100 using 1X wash buffer. Samples having higher concentration of bound C3 should be diluted appropriately and assayed again so the measured optical density falls within the standard curve.

**SAMPLE STORAGE**
Use serum or heparinized plasma samples immediately after collection or store sample preferably below -70º C for future use. Avoid repeated freeze-thaw cycles. Sample stored at -20º C can also be used.

**CAUTION**
Hemolyzed samples and samples exposed to higher temperatures are not suitable for measurement of C3. The use of serum is preferred for C3 measurement.

Note: The reagents should be brought to room temperature before using the test kit. Bring all solutions to room temperature (20-25°C).

ASSAY PROCEDURE
Any debris observed should be removed by centrifugation at 1500g for 10 minute at room temperature from the samples prior to sample dilution.

1. Dilute samples with 1X wash buffer. We recommend 1:50 to 1:100 dilution of the samples.
2. In the first step leave the first two rows A1-H1 and A2-H2 containing standards as it is without removing the plate sealer. These wells do not receive any solution in the first step.
3. Wash the wells in the rest of the plate (A3-H3 to A12-H12) with 200 µl of 1X wash buffer for two to three minutes.
4. Pipette 100 µl of sample per well. It is recommended to run the assay in duplicate wells.
5. Incubate the plate for ninety minutes at room temperature (20 to 25ºC).
6. Wash 4-times with 300 µl of wash buffer using a squirt bottle or automated plate washer. Allow buffer to stay in the wells for 2 minutes between each wash.
7. Add 100 µl of anti-C3 antibody (diluted to 1X with 1X wash buffer) to each well and incubate the plate for sixty minutes at room temperature (20 to 25ºC).
8. Repeat wash as in step 6.
9. Add 100 µl of anti-C3-HRP-Conjugate to all the wells and incubate for another sixty minutes at room temperature (20 to 25ºC).
11. Add 100 µl of color development reagent and watch for appropriate development of color. It will take about 5 to 15 minute for color to develop, depending on the amount of C3 present on the CIC. During the color development gently tap the plate occasionally to avoid trapping air bubbles in the substrate solution.
12. Stop the reaction by adding 50 µl of stop reagent, after the desired optical density is reached.
13. Read the plate using a microplate reader at 450 nm.
14. Plot the standard values against the known concentration and using the linear equation calculate the sample values (y = a + bX).
15. Use the portion of the curve that is linear for calculating the values.

It is preferred to use plate shaker during incubations to obtain uniform binding.

CALCULATION OF RESULTS
Make a spreadsheet and enter the data. Average the duplicate readings for standards, controls and samples. Subtract the average zero standard optical density; if the function is available in the machine the plate reader does this.

Create a standard curve by plotting the mean absorbance for each standard on the y-axis against the concentration on the x-axis and draw the best-fit curve through the points on the curve. Discard the values, which distort the curve or add undesired error. Calculate the slope and intercept use these values in a linear equation y = a+bX to calculate the sample values.

LIMITATION OF ASSAY
THE ASSAY IS FOR RESEARCH USE ONLY AND NOT FOR USE IN DIAGNOSTIC PROCEDURES

- The samples should be prepared as described.
- It is important that the sample values fall within the linear part of the standard curve.
- The kit should be used within the expiration date.
- Variations in operator, pipetting technique, washing technique, incubation time, incubation temperature, kit age and presence of interfering agents in the serum and plasma samples may cause variation in binding.
